TITLE: Thermomechanical characteristic of the molecular weight of linear polymers, with natural rubber as the example

PERIODICAL: Akademiya nauk SSSR. Doklady. v. 149, no. 6, 1963, 1384-1386

TEXT: Theoretical and experimental studies have demonstrated the possibility of estimating the molecular weight of polymers on the basis of the investigation of its thermomechanical properties. An equation has been offered relating the molecular weight  $M$  to the embrittlement temperature  $T_e$  and pour point  $T_{p.p.}$ . The pour point of a polymer can be largely established by determining the end point of penetration  $T_{ep}$  found from the thermomechanical curve, which characterizes the viscosity and even molecular weight of the polymers. The authors verified this by their studies of specimens of natural rubber with different molecular weight. By special experiments they established that the value of  $T_{ep}$  is the same at temperatures below the embrittlement temperature and at room temperature, when recording the thermomechanical curve. Thus it is possible to determine  $T_{ep}$  as a function of molecular weight. This method can also be applied to crystallizing polymers, provided the melting point of the crystalline phase is below the pour point. There are 2 figures.

TITLE: Multiple investigation of the crystallization of polychloroprene rubber -  
Nairit

SOURCE: AN SSSR. Doklady, v. 150, no. 3, 1963, 608-611

TOPIC TAGS: crystallization, polychloroprene rubber, elasticity, crystallinity

ABSTRACT: The crystallization process in Nairit was studied by thermo-mechanical, thermographic and X-ray methods. The deformation of freshly-prepared polymer faded out (indicating crystallization) in 15 minutes at 0°, in 2 hours at room temperature. Thermomechanical curves showed maximum crystallinity for unheated samples and maximum elasticity on heating to 50° and holding at room temperature for one hour, elasticity decreasing with prolonged holding. The plateau of the peaks in a thermogram is dependent on degree of crystallinity. Thermomechanical curves can be used to evaluate degree of crystallinity. Supplementary X-ray analyses are necessary to determine absolute percentage of crystallization. The kinetics of Nairit (and other elastomers) crystallization can be studied by a combination of these methods. Orig. art. has: 4 figures.

TITLE:

Crystallization of natural rubber

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 145, no. 5, 1962, 1077-1080

TEXT: The crystallization in natural rubber was studied by thermomechanical and X-ray diffraction analyses. In the range from  $-80$  to  $60^{\circ}\text{C}$  and under alternating loads of 0.64 and 3.2 kg/cm, a sharp increase of deformability occurs at  $0^{\circ}\text{C}$ , due to fusion of the crystallites. From  $-35$  to  $0^{\circ}\text{C}$ , the deformability is smaller owing to an additional crystallization and solidification of rubber near optimum crystallization temperature ( $-25^{\circ}\text{C}$ ). When rubber is cooled from room temperature to below vitrification temperature within 1 hr, practically no crystallites are formed except at the optimum crystallization temperature, since crystallization takes longer at other temperatures; it can be completely prevented by quickly freezing the rubber with liquid nitrogen. The melting point of the crystallites depends on their temperature of formation. In "tanned" rubber melting at  $\sim 45^{\circ}\text{C}$ , the deformability in the highly elastic state is much lower than in rubbers

Card 1/3

## Crystallization of natural rubber

S/020/62/145/005/015/020  
B106/B144

crystallizing at low temperatures, but rises suddenly at 45 - 48°C. Heating the "tanned" rubber to >50°C destroys the crystallinity. Such samples do not show any jump in the deformability at 0°C or 45°C, but their deformability on transition to the highly elastic state (-60°C) is much higher than in the initial rubber. When a rubber heated previously to 53°C is kept at -25°C for 1.5 hrs, crystallites are formed which melt at 0°C. When "tanned" rubber is being cooled to low temperatures, crystallization occurs without the temperature needing to be kept constant for long. The crystalline phase, formed at room temperature, therefore initiates crystallization at low temperatures. X-ray analyses showed that the crystalline phases formed at different temperatures were independent of their melting points. This is explained by the fact that at -25°C the crystallites are formed so quickly that no equilibrium is attained. The low melting point may be due to strong internal stresses and/or to the small size of quickly formed crystallites. The results of the thermomechanical and the X-ray analyses are complementary and this combination may be useful for studies of other polymers also. There are 4 figures. TITLE: Thermomechanical curves of several rubbers

PERIODICAL: Kauchuk i rezina, no. 8, 1962, 3 - 6

TEXT: The thermomechanical curves of several rubbers under various loads, within a temperature interval from -120 to +450°C, were recorded, using an automatic recorder. The method of continuous weight application was used. The resultant curves reflected the characteristic qualities of the investigated rubbers, leading to the derivation of certain quantitative units:  $T_g$  - vitrification temperature,  $T_f$  - fluidity temperature; and a relative evaluation of the degree of deformation of the material at any given temperature. The curves were plotted over temperature - deformation coordinates by a recorder designed at the Kazan' branch of the Academy of Sciences of the USSR. The thermomechanical curves produced are shown in figures. The CKД (SKD) curve is thought to be influenced by the presence of a crystalline phase. The figures obtained for this rubber under a

AUTHOR: Teytel'baum, B. Ya.

TITLE: Thermo-mechanical curves for polymers under continuous load

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 4, no. 5, 1962, 655-661

TEXT: Two methods of establishing temperature-deformation curves of polymers are compared, namely (A) that of V. A. Kargin (periodically loading and unloading the specimen at each stage of heating) and (B) that of Ye. I. Regirer and M. S. Kalantarova (continuous load with rising temperature). In both methods the plateaux of the curves characterize the highly elastic range, with the rise that characterizes plastic flow beginning at yield point  $T_T$ . Complete penetration of the indenter corresponds to point  $T_K$  at which the rising curve intersects the line of 100% deformation. With method B, however, the plateau does not indicate that deformability is unchanged, but rather, that an increase in deformability is prevented by the greater rigidity of the polymer. On the development of a space lattice, in the high-elasticity range ( $T_c < T_o < T_T$ )

Card 1/3

S/190/62/004/005/005/026  
B139/B138

Thermo-mechanical curves for ...

(where  $T_c$  is brittle point and  $T_o$  the temperature at which space lattices form), and in the viscous range ( $T_o > T_T$ ), method B produces plateaux while method A shows a reduction in deformability to nearly zero. The rise in both curves at  $T_T$  corresponds to transition to the viscous state, not of the original polymer, but of the destructible product of their cross-linking. The B-type curve reflects thickness variations which are not only due to externally applied pressure but also to "post-polymerization", destruction processes with gas liberation and the effects of thermal expansion. B-type curves contain more information, but since, however, different causes may produce apparently similar curves their correct interpretation calls for control operations such as varying the load, rate of heating and nature of the gaseous medium, interrupting the experiment at a certain stage and repeating it later, after the specimen has cooled, and comparison with the results of independent studies. This is similar to thermographic analysis which first became practicable through the development of automatic recording methods for heating curves, by Le Châtelier, N. S. Kurnakov, and Saladen. There are 4 figures.

TITLE:

Study of thermal transformations of some rubbers by means of  
thermomechanical curves

PERIODICAL:

Akademiya nauk SSSR. Doklady, v. 140, no. 5, 1961, 1132-1135

TEXT: The authors attempted the continuous recording of thermomechanical curves for rubbers by an improved method (B. Ya. Teytel'baum, Peredovoy nauchno-tekhnich. i proizvod. opyt, Tsentr. inst. tekhn.-ek. inf., ser. 32, 1961, no. 4/2). Recording was performed automatically under constant load and with uniform temperature increase in nitrogen atmosphere. An ЭПН-09 (EPP-09) electronic potentiometer was used as recorder. The recording chart was advanced according to the deformation. Rubber specimens (4 mm diameter, 2 mm height) were tested at -120 to +450°C. The rate of heating was 2 deg/min, the load 3.2 kg/cm<sup>2</sup>. Deformation is indicated in relative percents. The following was found: (1) For all natural rubbers (smoked sheets), a "stop" was observed on the curve corresponding to the melting

Card 1/43

Study of thermal transformations...

of the crystalline phase at  $\sim 0^{\circ}\text{C}$ . If the sample is controlled by thermostat at the optimum crystallization temperature ( $-25^{\circ}\text{C}$ ), the step already appears for slight deformation. This confirms its relationship with the crystalline phase. Such an affect was not observed in any synthetic rubber. (2) Butadiene rubbers  $\text{CKB}(\text{SKB})$ ,  $\text{CKB}(\text{SKV})$ ,  $\text{CKBM}(\text{SKBM})$  and piperylene rubber  $\text{CKP}(\text{SKP})$  synthesized by alkaline catalysts showed characteristic vitrification temperatures. The thermomechanical curves ascended immediately after exceeding the vitrification temperature. Thus, plastic deformation immediately occurs in these rubbers besides elastic deformation. (3) Butadiene rubber of the type  $\text{CKLD}(\text{SKLD})$  synthesized by a lithium catalyst and having low plasticity behaved differently. Fig. 3 shows thermomechanical curves for SKLD rubbers of high and low plasticity. Cross linking was found to occur by heating to  $250^{\circ}\text{C}$ . If SKLD rubbers of high plasticity were heated to  $250^{\circ}\text{C}$ , they showed the same thermomechanical curve as rubbers of low plasticity. Other butadiene rubbers such as SKB,  $\text{CKD}(\text{SKD})$  (synthesized by a complex catalyst) behaved similarly. In natural rubbers, isoprene rubbers  $\text{CKI}(\text{SKI})$  and piperylene rubber SKP, no cross linking was attained by heating to  $250^{\circ}\text{C}$ . Therefore, butadiene rubbers may be easily distinguished from other rubbers by heating them to  $250^{\circ}\text{C}$  and

TITLE: The method of recording the thermomechanical curves of polymers

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 3, no. 4, 1961, 594-601

TEXT: This paper reports on the design of an apparatus for the continuous recording of thermomechanical curves (TMC) and on some experiments conducted. Fig. 1 shows a schematical drawing of the apparatus. O is the sample contained in a vessel of 4 mm inner diameter and 2 mm height. It is part of the heater S (aluminum). S is cooled with liquid air before the beginning of the experiment by means of the Dewar vessel A, subsequently heated at constant temperature rise. The linear increasing voltage of  $\Delta \Pi H$ , the thermocouple TY and the electronic relay  $P_2$  serve for this purpose.  $P_2$  switches in the heating current as soon as the emf of TY has reached the voltage of  $\Delta \Pi H$ . The sample is loaded with the weight  $\Gamma$  of the stamp II, the weight of which is equalized by the scale beam K and counterweight. The contact needle M is fixed at the end of K. The vessel with the samples is

• B101/B207

The method ...

fixed at the cross beam T by means of rods. The micrometer screw M forms part of T and is moved by means of a CA-2 (SD-2) synchronous engine. (Insulators are between K and U, as well as between T and M). U separates from M when the sample is deformed (falling of the stamp П). Subsequently, the relay P<sub>1</sub> switches in the engine (a) of the record chart of the ЭПП-09 (EPP-09) recorder and SD-2, which are synchronous until contact is re-established between U and M. The maximum recording rate of deformation depends on the rpm. of the Warren engine. The temperature of the sample is measured with the thermocouple TM, which is connected to the input (b) of EPP-09. The cold junctions XC are kept at 20°C by means of the thermostat. The potentiometer ПC permits the recording of both positive and negative temperatures. At (c), N<sub>2</sub> is blown through. A special device was designed to bring various diagrams to the same scale by means of projecting the record chart located on an inclined glass plate onto a horizontal table. Fig. 3 shows the TMC of polyvinyl chloride at different stress. At 100, 125, and 150°C, the diagrams of Fig. 4 were obtained herefrom. Linear function between deformation and stress could be observed only in highly elastic state (up to 100°C). At higher temperatures, a deviation from linearity was observed owing to plastic deformation. Fig. 5 shows the dependence of the vitrifica-

The method ...

tion temperature  $T_v$  and the softening point  $T_g$  on the stress. The real  $T_g$  was determined by recording  $T_g$  at various small stress by extrapolation with respect to zero stress. Similar investigations were also carried out on polymethyl methacrylate and the copolymer from the allyl dichloro vinyl ester of phenyl phosphinic acid and 3% methyl methacrylate provided by N. I. Rizpolozhenskiy and A. A. Muslinkin. The optimum stress was found to depend on the kind of the polymer to be investigated. At high stress,  $T_v$  can be accurately determined, while the determination of  $T_g$  requires a small load. Furthermore, the course of TCC was found to be highly dependent on the preparation of the sample. Fig. 8 shows this for polymethyl methacrylate. V. A. Kargin and V. L. Tsetlin are mentioned. There are 9 figures and 8 Soviet-bloc references.

TITLE:

Spectrophotometric Investigation of Picrates of Aromatic Hydrocarbons in Solution

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 128, Nr 1, pp 106-109 (USSR)

ABSTRACT:

In the present paper the authors attempted to solve the problem as to whether aromatic hydrocarbons may be determined on the basis of light absorption of their picrates. As a solvent 1,2-dichloro ethane was used which solves picric acid and hydrocarbons as well as picrates. In a relatively wide spectral range the absorption curves were plotted and for a series of solutions the molar extinction coefficients  $\epsilon$  were computed (Fig 1). Absorption spectra of the solutions investigated may be divided into 3 ranges: In the shortwave range (222-300 m $\mu$ ) absorption bands characteristic of naphthalene hydrocarbons occur. In the medium range there is the absorption maximum of picric acid (340 m $\mu$ ). For differently concentrated solutions and solutions with heterogeneous hydrocarbons the extinction curves are equal. The long-wave range is characterized by the absorption of picrates. Besides naphthalene and its methyl-substituted derivatives, also individual non-condensated aromatic

Card 1/3

Spectrophotometric Investigation of Picrates of  
Aromatic Hydrocarbons in Solution

SOV/20-128-1-28/58

hydrocarbons were investigated. With all solutions investigated absorption edges are almost parallel (Table 1) in the visible part of the spectrum. The investigation was carried out on the spectrophotometer SF-4 at room temperature. The following investigation results were found: By formation of picrates of aromatic hydrocarbons, the absorption edge of picric acid is shifted towards the longwave range. The amount of shifting depends on the nature of the hydrocarbon and on the concentration of the solution. With an increase in the number of alkyl groups in the hydrocarbon molecule, the absorption edge is shifted correspondingly. The shifting of the absorption edges is hardly influenced by a complication in the structure of alkyl groups, or by a variation of their position in the ring. This shifting may also serve at a certain optical density - just as the absorption quantity on a certain wave length - for the determination of aromatic hydrocarbons by the spectrophotometric and colorimetric method. The authors thank L. A. Mukhamedova and Ye. A. Robinson for providing the preparations. There are 2 figures, 1 table, and 7 references, 5 of which are Soviet.

On Isotherms of the Properties of Binary Liquid Systems of Which One Component Is Isomerized by the Influence of the Other (Ob izotermakh svoystv dvoynykh zhidkikh sistem, odin iz komponentov kotorykh izomerizuyetsya pod vliyaniyem drugogo)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 2, pp 337-340 (USSR)

ABSTRACT:

The author has discussed the problem mentioned in the title from a general point of view, and derived types of isotherms for systems of this kind. In addition to this he has shown the peculiarities and differences in these isotherms as compared with those which are related to systems with formation of additive compounds. In the investigation of the interaction between the components in the liquid phase and in the binary phase the formation of additive compounds is usually assumed to occur on the pattern  $mA + nB \rightleftharpoons A_m B_n$ .

However, the chemical interaction of the components is by no means fully explained by this case. It may occur on the

Card 1/4

On Isotherms of the Properties of Binary Liquid  
Systems of Which One Component Is Isomerized by the  
Influence of the Other

SOV/20-125-2-27/64

pattern of a double exchange. In this process 4 types of molecules are in equilibrium in the liquid phase:  $AR + BR' \rightleftharpoons AR' + BR$ . The investigation of the isotherm shape is far more complicated with regard to this reaction type than it is with regard to the formation of additive compounds. In respect of complex molecules (hypothetically designated by  $ACR$ ), a molecule regrouping  $ACR + BR' \rightleftharpoons AR'C + BR$  may occur. The special case of  $R' = R$  is of particular interest. In this case, an isomerization  $ACR \rightleftharpoons ARC$  takes place, in which the 2nd component does not formally participate, but in which it actually plays the part of a catalyst. In the absence of this 2nd component, isomerization will not occur. Furthermore, 2 cases are discussed: 1) The intensity of the property of the isomerizing component is higher than that of the other one ( $BR$ ). In this case there are two possibilities: a) The intensity of the properties  $ARC > ACR$  (Fig 1, patterns 1a and a'); b)  $ARC < ACR$ . Case 2) The intensity of the property of the isomerizing component is lower than that of the other one ( $BR$ ). Here, too, there are two possibilities: a)  $ARC > ACR$

Card 2/4

On Isotherms of the Properties of Binary Liquid  
Systems of Which One Component Is Isomerized by the  
Influence of the Other

SOV/20-125-2-27/64

(Fig 1, pattern 2a); b) ARG (ACR). From the above-mentioned facts we arrive at the conclusion that the isotherms of such systems as contain a component which is isomerized by the action of the 2nd component may possess the same geometrical properties as those of systems with the formation of additive compounds: curvature, extreme values, deflection points. By way of conclusion a characteristics of systems with isomerization are set forth. From them it can be seen that systems have to be studied at different temperatures and at different reaction durations if the type of interaction concerned is to be differentiated from the ordinary formation of additive compounds. One instance of isomerization is the regrouping, discovered by A. Ye. Arbuzov (Ref 4); of phosphoric acid esters into esters of the alkylphosphinic acids by the action of halogen alkyls. There are 1 figure and 5 Soviet references.

TITLE: Brief Communications. A Photometric Picrate Method of  
Determination of Naphthalene in Mixtures With Phenol  
PERIODICAL: Zhurnal analiticheskoy khimii, 1960, Vol 15, Nr 1, pp  
119-120 (USSR)  
ABSTRACT: This simple and accurate method is based on the difference  
of the bathochromic shifts of naphthalene and phenol  
picrates. Quartz optics are not necessary (FEK-M  
spectrophotometer was used). 0.1 Dichloroethane  
solutions of picric acid and naphthalene are used.  
Picrates of phenol absorb at about 412-425 m $\mu$ ,  
and those of naphthalenes at 455 m $\mu$  and up. The  
concentrations are determined from calibration curves.  
The accuracy of this method is up to 1%. There is 1  
figure; 1 table; and 3 Soviet references.

TITLE: Determination of the molecular weight of linear polymers by the thermo-  
mechanical method

SOURCE: Vysokomolekulyarnyye soyedineniya, v. 7, no. 2, 1965, 299-304

TOPIC TAGS: thermomechanical method, rubber, molecular weight

ABSTRACT: A new rapid and accurate method has been proposed for determining the molecular weight of amorphous linear polymers, based on thermomechanical curves. The method is based on the correlation of the temperature ( $T_k$ ) of the completion of penetration of an indenter into the specimen with the intrinsic viscosity ( $[\eta]$ ) of solutions of the specimen, and, hence, its molecular weight ( $M$ ). Once a  $T_k$  versus  $M$  calibration curve has been plotted, the molecular weight determination is reduced to the plotting of a thermomechanical curve to find  $T_k$  and reading  $M$  from the calibration curve. In contrast to existing methods, the new method does not require the determination of the glass-transition flow and temperatures. It is applicable to polymeric homologs which do not exhibit high elastic properties. The correlation

Card 1/2

L 27185-65

between  $T_k$  and M or  $n$  was shown experimentally for natural, isoprene, chloroprene  
 (KR-A-type Nairit) and SKN-40 nitrile rubbers, polyisobutylene, and liquid  
thiocol. The thermomechanical measurement conditions which will ensure a reliable  
 correlation were determined. Orig. art. has: 7 figures. [SM]

TITLE:

Automatic half-submerged arc welding of aluminum equipment

PERIODICAL:

Referativnyy zhurnal, Metallurgiya, no. 4, 1962, 23, abstract 4E115  
("Montazhn. i spetsializor. raboty v str-ve", 1961, no. 11, 3 - 7)

TEXT:

The Promtekhmontazh and Orgproyekttekhmontazh trusts have successfully mastered and introduced automatic half-submerged arc welding (svarka poluotkrytoy dugoy po slovyflyusa) of Al containers. These containers are made of AlYK (AlUK) aluminum, are 2.3 m in diameter and 10.5 m long, and have 8 mm thick walls and two spherical bottoms of 10 mm thick sheet. 2 mm AE1 (AD1) electrode wire and AH-Al (AN-Al) flux were used for the welding. The metal and welding wire were prepared for welding by normal means. The optimum flux layer - 8 to 9 mm - was found empirically. Welding was done with one electrode and two wires (by the split electrode). ATC-17MY (TS-17MU) tractor was used for annular welds and an AAPI-500 (ADPG-500) tractor for the longitudinal welds of the shells and the butt welds of the bottoms; the tractors were adapted for half-submerged arc welding. A special production line was organized for making the elements, and assembling

and welding the equipment on an assembly site. For welding the annular welds dispensable (neostayushchiyesya) backing rings were used.

 TITLE: Comparison of Numbers in the Czech Number System (Sravneniye  
 chisel v Cheshskoy sisteme schisleniya)  
 PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol 121, Nr 5, pp 807-810 (USSR)  
 ABSTRACT: Let  $2 = p_1 < p_2 < \dots < p_n$  be positive prime numbers. The Czech  
 system is a number system in which a number is represented by  
 the totality of its smallest non-negative remainders mod  $p_1, p_2, \dots$   
 $\dots, p_n$ . Under restriction to non-negative integers smaller than  
 the product  $p_1 p_2 \dots p_n$ , the author describes a method for the  
 comparison of the magnitude of two numbers given in the Czech  
 system. The method is valid if  $p_1 = 2$  only. Let  $M = p_1 p_2 \dots p_n$ .  
 Numbers of the first half are numbers  $a$  for which  $0 \leq a < \frac{M}{2}$ , for  
 the numbers of the second half holds  $\frac{M}{2} \leq a < M$ .  
 Theorem: Let  $a$  and  $b$  belong to one half. Necessary and sufficient  
 that  $a \geq b$ , is that  $[a-b]$  belongs to the first half.  
 Here  $[a-b]$  is an especially defined so-called table difference.  
 The above theorem permits to reduce the comparison of two numbers  
 to the answering of the question, to which half there belongs  $a$

Card 1/2

Comparison of Numbers in the Czech Number System

SOV/20-121-5-11,50

given number. The method demands  $1+6(n-2)$  steps maximally.  
There is 1 Czecho-Slovakian reference.

ABSTRACT: This Author's Certificate introduces a device for protecting inspection ports in high temperature vacuum installations. The device consists of a cassette made of a material resistant to metal vapor. The device is designed for assuring continuous visual observation and photography of the various processes taking place inside the vacuum chamber. The unit is equipped with a device which takes up the film material and the tape on which the surface.

CA Terpk, B

Coagulation of silver halides by electrolytes and the Wolfgang Ostwald theory of the activity coefficient. H. Terpk, B. Muthleiss, and K. Schulz (Univ., Zagreb). *J. Polym. Sci. A-1*, 20, 1-15 (1982) (English summary). Review of the exptl. basis of the activity-coeff. concept, including the equation  $f_{\pm} = \text{const.}$  (Wo. Ostwald), indicated that this equation is approx. and holds best for concns.,  $C_{\text{st}}$ , greater than  $10^{-2} N$ , and for the univalent coagulating cations. Choice of the concn. range  $10^{-2}$  to  $10^{-3} N$ , and production of the colloid in the nascent state avoided the disadvantages of working with high concns. of the sol, namely: (1) the dialysis procedure, hence the "denaturation" of the colloidal particle; (2) the adverse effect of ion adsorption on the colloid, hence the primary cause of deviation of  $f_{\pm}$  from constancy in the range of high  $C_{\text{st}}$ , which was already evident from Ostwald's expts. (1911, 31, 811-7). For Ag halides at low  $C_{\text{st}}$ ,  $f_{\pm}$  varies for a given stabilizing ion with the concn. ( $C_{\text{st}}$ ) and with the valence of the coagulating cation,  $z$ . The chem. nature of the stabilizing ion is another factor significantly

affecting the linearity of  $f_{\pm}$  as a function of  $C_{\text{st}}$ ,  $z$  being next in importance. For AgI, the deviation is least when  $z = 1$  ( $K^+$ ). The activity coeff. rises nearly proportionally with  $z$ , as shown by the expts. with  $Ba^{++}$  and  $La^{+++}$  ions. For AgBr  $f_{\pm}$  rises with  $z$ , but no proportionality is observed. (Intersection of the  $f_{\pm}-C_{\text{st}}$  curves obtained with  $K^+$  and  $Ba^{++}$ , and an unexpectedly abrupt rise for  $La^{+++}$ ). For AgCl there is no parallelism between  $f_{\pm}$  and  $z$ , the rise following a distorted order:  $Ba^{++}$ ,  $La^{+++}$ ,  $K^+$ . The relative constancy of  $f_{\pm}$  at  $C_{\text{st}}$  values higher than  $10^{-2}$  is due to a slight effect of adsorption, namely, the dominant cation is adsorbed on the colloidal particle making the ratio  $m/C_{\text{st}}$  nearly negligible (where  $m$  is the molar concn. of the coagulating salt). This effect is the more pronounced, the higher the valence,  $z$ , of the dominating cation. The rise of  $f_{\pm}$  at low  $C_{\text{st}}$  values is in part due to a considerable increase of the ratio  $m/C_{\text{st}}$  in the region below  $10^{-2} N$ . The concn. of the stabilizing ion was found almost without effect on  $f_{\pm}$  when kept below  $10^{-2} N$ . The "structure" of the cross-section of the boundary layer sol/coagulum is also an important factor, detg. for  $f_{\pm}$  the extent of its deviation from linearity. This additive property varies with the conditions of expt.: (1) Direction and extent of displacement of the disocn.  $\rightleftharpoons$  assocn. equil. in the liquid phase. Both these factors can be evaluated approx. from the value of  $k^*$ , which is the crit. distance

between the coagulating and the stabilizing ion, as well as from  $d_{\text{min}}$ , which is the diam. of the double-layer atm. It was shown previously that  $d_{\text{min}}$  is a function of  $k^1$  and of the other exptl. conditions, such as the d. of the elec. charge on the colloidal particles of the coagulum, etc. (C.I. 37, 4319; 42, 7602e). (2) The statistical distribution of elec. charges in the boundary layer, which is a function of  $z$  and of the concn. gradient of the stabilizing ion, as well as of the other ions present in the sol. (3) The nature and configuration of all component ions in the liquid phase. The detn. of the crit. concn. of the sol.,  $C_{\text{crit}}$ , was done with high accuracy by measuring the changes with time in the intensity of the Tyndall cone (Težak, C.I. 30, 2470). The expts. were performed on a series of aq.  $\text{AgNO}_3$  solns. ( $4 \times 10^{-4}$ ,  $2 \times 10^{-4}$ ,  $4 \times 10^{-4}$ , and  $1 \times 10^{-3} \text{ N}$ ). For each concn. of  $\text{AgNO}_3$ , the concn. of the stabilizing ion was varied gradually from that equiv. to the  $\text{Ag}$  ion to the  $1 \times 10^{-3} \text{ N}$ . The valence,  $z$ , of the dominating cation was varied from 1 to 3 by experimenting separately with  $\text{K}^+$ ,  $\text{Ba}^{++}$ , and  $\text{La}^{+++}$  as nitrates. The coagulum was formed by slowly decanting 5 cc. of the  $\text{AgNO}_3$  soln. into 5 cc. of the aq. soln. of  $\text{HCl}$ ,  $\text{HBr}$ , or

$\text{KI}$  plus  $\text{HNO}_3$ . In each case the desired coagulating salt was introduced beforehand. The mixing was achieved by decanting back and forth repeatedly the prepd. sol. from one test-tube into another for 20-25 sec. The test-tubes with the sol were kept at  $20^\circ$  in a thermostat during the course of the expt. The chamber of the Tyndallometer was also kept there during the readings. The latter were taken after mixing, at intervals of 1, 2, 4, 5, 10, 20, and 60 min. in 3 spectral regions: blue, green, and red. Next, the tyndallograms were plotted, with the readings (converted into nephelometric values) as ordinates and with the logs of the concn. of the stabilizing ion as abscissas. The crit. concn. of the coagulating cation,  $C_{\text{crit}}$ , was evaluated from the slope of the tyndallometric curves corresponding to the 10-min. interval. This was done by extrapolating to zero turbidity, which approximated best the value obtainable by direct analysis. The  $f_1$  value was calcd. from above data with the aid of the Wo. Ostwald equation after converting  $C_{\text{crit}}$  into  $m_2$  values. In these calcs. the concns. of all components were adjusted for the total vol. of the sol (10 cc.). The instrument used for light-intensity measurements was a combination of a nephelometer (Zeiss) and a photometer (Puffrict).

TEAK. B

*An analysis of the present state of chemical literature and the need for the establishment of an international chemical periodical* Belo Tefak (Ljub. Zagreb, Croatia, Yugoslavia) Arch. Sci. 23:208-17 (1951) in English --There are about 4000 periodicals of chem. interest, 400 of which are used frequently by chemists. Important purely chem. journals and journals closely related to chemistry number 100. Of these 100 journals, 50% cover general chemistry, 35% cover all fields of chemistry, 10% cover physical chemistry, and 5% miscellaneous fields. Of the 4000 journals, 40% are in English, 25% in German, 10% French, 2% Russian, 7% Spanish and Portuguese, 4% Italian, 5% English-French-German, and 11% in other languages. The no. of copies, printed pages, and words of publications in English well outweigh the tot. no. of all the others. Reasons are given for establishing an international chem. periodical and an organizational plan is outlined, with the Intern. Union of Pure and Applied Chemistry as owner. D. S. Hessemer.

CA

Coagulation effects of thorium nitrate on aqueous sols of silver halides in *status nascenti*. I. The coagulation curve and the coagulation value of thorium nitrate. B. Tezak, B. Matijevic, and K. Schulz (Univ. Zagreb, Yugoslavia): *J. Am. Chem. Soc.* 73, 1602-5 (1951).—The effects of  $\text{Th}(\text{NO}_3)_4$  in various concns. on aq. systems of  $\text{AgNO}_3$ ,  $\text{HBr}$  and  $\text{AgNO}_3$ - $\text{KBr}$  were investigated by tyndallometric measurements. By systematic diln. of  $\text{Th}(\text{NO}_3)_4$ , the coagulation curve shows 4 distinct regions, 2 stabilization regions, and 2 coagulation regions. For the dild., negatively charged  $\text{AgBr}$  sols in *status nascenti* (system  $6 \times$

$10^{-4} \text{ N AgNO}_3$ - $2 \times 10^{-3} \text{ N HBr}$ ) the first limit of coagulation-stabilization ( $0.02 \text{ N}$ ) represents the crit. concn. of coagulation where the coagulating ion is  $\text{NO}_3^-$ , whereas the stabilizing action is caused by the  $\text{Th}$  complexes of pos. sign in the adsorbed state. Under otherwise the same conditions (system  $2 \times 10^{-4} \text{ N AgNO}_3$ - $4 \times 10^{-3} \text{ N HBr}$  and  $4 \times 10^{-3} \text{ N Th}(\text{NO}_3)_4$ ) the coagulation concn. is shifted from  $2 \times 10^{-3} \text{ N}$  of  $\text{KNO}_3$  to  $6 \times 10^{-3} \text{ N}$  of  $\text{K}_2\text{SO}_4$ . The second limit of stabilization-coagulation ( $\sim 1 \times 10^{-2} \text{ N Th}(\text{NO}_3)_4$ ) and the acidification of the medium. The third limit of coagulation-stabilization ( $\sim 3 \times 10^{-2}$  and  $\sim 3 \times 10^{-2} \text{ N Th}(\text{NO}_3)_4$ ) gives the coagulation values of  $\text{Th}$  complexes (probably trivalent and quadrivalent, resp.) on the negatively charged  $\text{AgBr}$  sol. II. The features of stabilization and the effects of "aging" of thorium nitrate solution. *Ibid.*, 1605-9.—The effect of various concns. of  $\text{Th}(\text{NO}_3)_4$  sols. on the coagulation of the  $\text{AgBr}$  sol in *status nascenti* of various concns. For such sols there were observed various effects on the crit. limits in the central stabilization region, the relations between the coagulation value of  $\text{K}_2\text{SO}_4$  and the concn. of  $\text{HBr}$  or  $\text{Th}(\text{NO}_3)_4$ , the effect of the acidity of the medium, and the effect of "aging" of the  $\text{Th}(\text{NO}_3)_4$  aq. soln. With decreasing concn. of  $\text{HBr}$  under const. concn. of  $\text{Th}(\text{NO}_3)_4$  the coagulation value of  $\text{K}_2\text{SO}_4$  decreases in a typical manner. The similar decrease of coagulation value was also found with decreasing concn. of  $\text{Th}(\text{NO}_3)_4$  soln. By "aging" of the  $\text{Th}(\text{NO}_3)_4$  soln., a characteristic shift of the stabilization-coagulation limit toward lower concns. was found. The phenomena observed were attributed to the complexation of different valencies in aq. solns. that manifest themselves in typical coagulation values. Thus, for negatively charged  $\text{AgBr}$  and the coagulation value for trivalent complex is  $\sim 4 \times 10^{-2} \text{ N}$ , for quadrivalent  $\sim 2 \times 10^{-2} \text{ N}$ , and for quadrivalent complex  $\sim 2 \times 10^{-2} \text{ N Th}(\text{NO}_3)_4$ . Harry H. Miller

TEZAK, B

Measuring coagulation processes. IV. Coagulation values of neutral electrolytes in mixtures water-alcohol for the negative sols of silver chloride in the nascent state. B. Tezak and J. Kratochvil (Pap. Sci., Zagreb, Yugoslavia). *Arch. Kem.* 24, 1-10 (1952) (English summary); cf. C.A. 46, 9912g. — 0.0002N AgNO<sub>3</sub> and 0.002N HCl were caused to react with each other in the presence of KNO<sub>3</sub>, Ba(NO<sub>3</sub>)<sub>2</sub>, and La(NO<sub>3</sub>)<sub>3</sub>, 0.002N in solns. in H<sub>2</sub>O which contained 0, 30, 50, 70, and 87% by wt. EtOH, and the Tyndall effect was measured after 10 min. with green light. In other expts. the concn. of the HCl was changed to 0.00022, 0.004, 0.008, and 0.006N. The critical concns. were obtained by extrapolation of the 10-min. pptn. curve to zero turbidity. Bjerrum's crit. distance  $d_c = \frac{z^+ z^- e^2}{2DkT}$ , where  $z^+$  and  $z^-$  are the valencies of the ions,  $e$  is charge of the ion in electrostatic units,  $D$  dielec. const. of the medium,  $k$  Boltzmann const., and  $T$  abs. temp., is a function of the corresponding critical concns. for the coagulation. Coagulation mechanism of hydrophobic sols (discussion of experimental results with silver halide sols in the nascent state). E. Matijević and B. Telak (Univ. Zagreb, Yugoslavia). *Kolloid-Z.* 125, 1-13(1952).—The important theories of coagulation are reviewed. The advantages of Ag halide sols, as well as of measurement of the sols in the nascent state, are pointed out. The various max. (concn., crystn., transition, isoelec.) of the coagulation curves are differentiated and discussed. The effects of opposite ion charge, amt. of ions, and sol concn. on the electrolyte coagulation of the Ag halide sols were established. The applicability of the coagulation method for detg. the complex-forming ions in electrolyte solns. was indicated with  $\text{Th}(\text{NO}_3)_3$  and  $\text{Al}(\text{NO}_3)_3$  solns. The coagulation theories of Wo. Ostwald and others were examd. critically, and agreement was indicated with Ostwald's views that the general state of the electrolyte soln. is of utmost importance in coagulation of hydrophobic colloid systems. S. I. A.

Formation of silver, zinc and aluminum hydroxides in alkaline medium obtained by hydrolysis of urea. B. Krcin and B. Terak (Univ. Zagreb, Yugoslavia). *Advan*

*Kem.* 25, 125-8 (1969) (English summary).—Following the technique by Wilhard (C.A. 45, 63) an attempt was made to ppt. the sols of  $\text{AgOH}$ ,  $\text{Zn(OH)}_2$ , and  $\text{Al(OH)}_3$  in an aq. medium at 80°, which contained urea in concn. from 0.001 to 0.1M, by keeping the nitrates of the metals in contact with the soln. for 1-6 hrs. The units of the hydroxide sols formed were detd. tydallometrically. If the urea soln. is first heated for 4-6 hrs. and then mixed with the nitrates the results are very different from those obtained when the nitrates are heated from the beginning with the urea soln.; this is explained by the great pH variations of the urea solns. of from 6.8 to 9.1, with respect to time and concn. The nitrate concns. were varied from  $5 \times 10^{-4}N$  to  $1 \times 10^{-1}N$ , with hydroxide formation setting in at approx.  $1 \times 10^{-2}N$  for all of them. Werner Jacobson

TEZAK, B

Congulation effects of  $\text{H}_2\text{P}_2\text{O}_7$  on silver halide sols in the nascent state. E. Matijevic and R. T. Zil. (Univ. Zagreb, Yugoslavia). *Trans. Faraday Soc.*, 1964, 60, 1111-1114. cf. C.A. 46, 6464a. Hydrophobic sols of Ag halides in the nascent state were pptd. with aq. solns. of  $\text{Na}_2\text{P}_2\text{O}_7$ ; in order to evaluate the effects correctly the pptn.  $\text{AgNO}_3$ - $\text{Na}_2\text{P}_2\text{O}_7$  had to be investigated first; the turbidograms show a max. that depends greatly on the concn. of  $\text{AgNO}_3$ . Addn. of  $\text{HNO}_3$  shifts the max. to higher concns. of  $\text{Na}_2\text{P}_2\text{O}_7$ . The pH was measured for every expt.  $\text{Na}_2\text{P}_2\text{O}_7$  in its action on AgBr in the absence or presence of 0.0005N to 0.0025N  $\text{HNO}_3$  shows 3 maxima and 3 minima in the curve, the first max. being independent of the  $\text{HNO}_3$  added, the pH there being 9-10. The second max. is identical with the one from the  $\text{AgNO}_3$ - $\text{Na}_2\text{P}_2\text{O}_7$  expt., and the third is very sensitive to  $\text{HNO}_3$  addn. Its stabilization and coagulation limits shift to higher concns. of  $\text{Na}_2\text{P}_2\text{O}_7$  if  $\text{HNO}_3$  is added. In the same expts. with AgI, the second max. disappears, but if there is an excess of  $\text{Ag}^+$  it reappears. AgCl expts. show three maxima, one being weak. Addn. of gelatin represses the third max. completely, the second develops after several hrs., and the  $\text{AgI}_2\text{O}_7$  max. appears completely. The last becomes smaller only in the presence of KBr. Electrophoretic measurements show that the pos. Ag halide sols change their charge under the influence of  $\text{Na}_2\text{P}_2\text{O}_7$ , a charge reversal that is the general property of tetravalent counterions.

3) Coagulation effects of aluminum nitrate and aluminum sulfate on aqueous sols of silver bromide in statu nascendi. Detection of polynuclear complex aluminum ions by means of coagulation measurements. E. Matijević and B. Tezak (Univ. Zagreb, Croatia, Yugoslavia). *J. Phys. Chem.* 57, 951-4 (1953); cf. *C.A.* 47, 6210i. — The crit. coagulation concn. of Al ions depends to a great extent on the age of the soln. Solns. of Al salts which had been artificially aged by warming showed a lower crit. coagulation concn. The pH of these solns. decreased during aging. On the basis of the data it is suggested that hydrolysis of moderately concd. solns. of Al salts leads to the formation of polynuclear ionic complexes according to  $2[Al(H_2O)_6]^{+++} + 2H_2O = [Al(OH)(H_2O)_5]^{++} + 2H_3O^+$ . The complexes formed by artificial aging of Al salt solns. were very stable. It was not easy to destroy the complexes either by subsequent diln. or by addn. of various amts. of mineral acids. H. L., Jr.

TEZAR, B020

TEZAR, B020

The precipitation processes as indicators for methoric structures. The effect of mixture of electrolytes of solvents and of colloid substances. Bodo Tefak, B. Matkovic, K. Schulz, J. Kratochvil, R. Wolf, and W. Cernicki (Univ. Zagreb, Yugoslavia). J. Colloid Sci. 1954, Suppl. 1, 118-27; C. C.A. 47, 6219i.—The characteristic max. and crit. limits encountered in detg. the aggregation of inorg. salts of low poly. in the presence of electrolytes can be used to obtain an insight into the structures of the methorical (i.e., interboundary) layer between crystal and solu. Examples given are: (1) the antagonistic action of mixts. of  $\text{La}(\text{NO}_3)_3$  with  $\text{KNO}_3$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{Mg}(\text{NO}_3)_2$ , or  $\text{MgSO}_4$  in the pptn. of  $\text{AgBr}$  or  $\text{AgI}$  sols; (2) the effect of dioxane on the ability of  $\text{KNO}_3$ ,  $\text{Ba}(\text{NO}_3)_2$ , and  $\text{La}(\text{NO}_3)_3$  to coagulate  $\text{AgBr}$  sols; and (3) the effect of small aints. of  $\text{AgI}$  on the pptn. of  $\text{AgBr}$  or  $\text{AgCl}$  sols.

# YUGO!

✓ Coagulation effects of potassium perchlorate, potassium chlorate, and sodium benzoate on positive silver bromide sol and of potassium sulfate on positive sols of silver halides. J. Herak and B. Tefak (Univ. Zagreb, Yugoslavia). *Arch. kem.* 26, 1-5 (1954) (in English). — Coagulation values of  $KClO_4$  (I),  $KClO_3$  (II), and  $NaOBr$  (III) for a pos.  $AgBr$  sol, and of  $K_2SO_4$  (IV) for pos.  $AgCl$ ,  $AgBr$ , and  $AgI$  sols in the nascent state in the presence of various concns. of the stabilizing ion ( $Ag^+$ ) were detd. Pptn. systems  $K$  halide ( $2 \times 10^{-4}$ ) —  $AgNO_3$  ( $2.5 \times 10^{-4}$  to  $1 \times 10^{-4}N$ ) in the presence of neutral electrolytes (I-IV) were investigated tyndalometrically (*C.A.* 46, 1842c). The concns. of the added electrolytes were gradually varied in the crit. coagulation region. The coagulation values were detd. from 10-min. concn. tyndalograms (*loc. cit.*) by extrapolating to zero turbidity. The results are represented in the diagrams of log coagulation values vs. log concn. of the stabilizing ion ( $Ag^+$ ). The coagulation values of I-IV first increase with increasing concn. of  $Ag^+$  (up to  $1 \times 10^{-4}N$   $AgNO_3$ ), attaining the max.

OVER ATT que

9. Hersh & B. Tagore

values for AgBr sol of I,  $4.5 \times 10^{-4}$ ; II,  $2.5 \times 10^{-4}$ ; III,  $4 \times 10^{-4}$ ; IV,  $8 \times 10^{-4}$ . In the middle region of Ag<sup>+</sup> concns. ( $1 \times 10^{-3}$  to  $5 \times 10^{-3}$ N) coagulation values of I and II are nearly const., but at the higher concns. of Ag<sup>+</sup> the coagulation values decrease again. This effect is supposed to be due to the additive coagulating action of NO<sub>3</sub><sup>-</sup> (from AgNO<sub>3</sub>) as a 2nd counterion. The coagulation values of III and IV decrease with increasing Ag<sup>+</sup> concns. immediately after reaching the max. Besides the additivity of coagulating action of counterions, the soly. of the compd. Ag ion-counterion is believed to play an important role. To support this assumption the diagram of log max. coagulation value vs. log soly. of the compd. Ag ion-counterion was constructed, with use also of the data from a previous paper (C.A. 48, 104003) given for the coagulation values of acetate, propionate, butyrate, and valerate ions. The coagulation values increase with increasing soly. of the compd.-stabilizing ion (Ag<sup>+</sup>)-counterion. The relation is linear except for the benzoate ion. The coagulation value of SO<sub>4</sub><sup>2-</sup> was about 0.1 to 0.05 times the values of I-III. This is considered to be proof of the validity of the Schulze-Hardy rule for pos. Ag halide sols. The sequence of the coagulation values of SO<sub>4</sub><sup>2-</sup> was in the order: AgI > AgBr > AgCl. This order is in accordance with the charge d. on the surface of sol particles. J. Kratochvil
